Results

For the TRT model:

	df	F	p-value
mechanism	2	0.8565	0.4247
cond	7	5.1524	0.0000

Both random effects, for Participant and Topic, are significant w.r.t alpha = 0.05.

For the FRT model:

	df	F	p-value
mechanism	2	0.5584	0.5722
cond	7	4.4390	0.0001

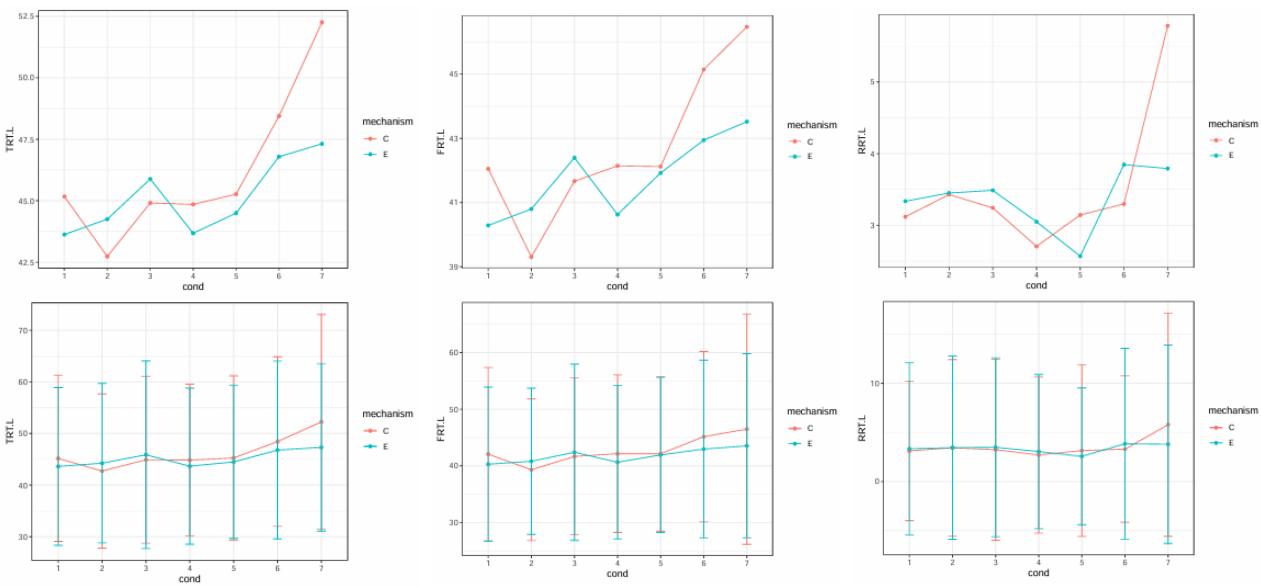
Both random effects, for Participant and Topic, are significant w.r.t alpha = 0.05.

For the RRT model:

	df	F	p-value
mechanism	2	1.4798	0.2278
cond	7	1.5334	0.1510

Both random effects, for Participant and Topic, are significant w.r.t alpha = 0.05.

The mechanism (coreference, encapsulation or none) has no significant influence on the total, the first and the re-reading time. The level of informativeness (cond, 0-7) has a significant influence on the total and the first reading time. For all three reading times, there are significant differences between individual participants and for the different topics.



***Research question 7**: ~~According to the level of informativeness, is the interaction effect as strong for encapsulation (E) compared to coreference (C)?~~ Is there an interaction between mechanism and condition?*

~~Hypothesis 9: Encapsulating mechanisms have the same interaction effect as coreferential mechanisms, according to their level of informativeness.~~

Possible formulation for hypothesis 9:
The average reading times of the categories of level of informativeness are just as large for encapsulation (E) as for coreference (C), i.e. there is no interaction between mechanism (E and C) and the level of informativeness (1 to 7).

-The standard deviation of the reading times per letter for encapsulation and coreference overlap largely within each condition for the total, first and re-reading time. This suggests that there is no interaction effect between mechanism (E and C) and the level of informativeness (1 to 7).

TRT per Letter	Estimates	Std.Error	p.value

Research question 1: *Does encapsulation (E) require greater processing efforts than coreference (C)?*

Hypothesis 1: encapsulation requires fewer processing efforts than coreference (E<C)

-See main results above. Encapsulation reduces the reading time per letter in the total, first and rereading time (c.p.). These effects are not significant.

-> Hypothesis 1 cannot be rejected.

Research question 2*: Does the level of informativeness influence in the processing efforts of anaphoric mechanisms (that is of encapsulation and coreference)?*

Hypothesis 2: the level of informativeness influences the processing efforts of anaphoric mechanisms.

-See main results above. The effects of condition 6 and condition 7 are significant for the reading time per letter in the total and first reading time as compared to condition 1. The higher levels of informativeness increase TRT.L and FRT.L significantly.

-> Hypothesis 2 cannot be rejected.

Research question 3 & 4*:* must be investigated exploratively from the bigger model results

Research question 5*: Does the presence of an anaphoric mechanism facilitate cognitive processing (= speeds up processing) compared to the absence of an anaphoric mechanism?*

Hypothesis 7: The presence of an anaphoric mechanism facilitates cognitive processing (CE0 > all other conditions).

-Both, coreference and encapsulation display lower average reading times when compared to no mechanism. However, this is not significant.

-> Hypothesis 7 cannot be rejected.

Research question 6*: Do taxonomic relations (conditions 1, 2, 3, 4, 6, 7) facilitate processing in comparison to relational relations (associative (condition 5))?*

Hypothesis 8: Taxonomical relations do not facilitate processing in comparison to relational relations.

-The effect of condition 5 is neither the biggest (for all three RT) nor positive (for RRT) among the effects of the categories of level of informativeness (c.p.).

-> Hypothesis 8 cannot be rejected.
